Näslund's (1936) height curve as a function of the tree's $d b h$ and the predicted height curve parameters $b_{0}$ and $b_{1}$ is $h=\left(d b h /\left(b_{0}+b_{1} d b h\right)\right)^{p}+1.3$. The power $p$ was 2 for Scots pine and birch (and other broadleaved species) and 3 for Norway spruce. The parameters $b_{0}$ and $b_{1}$ were predicted from the assortment volumes using models by Siipilehto and Kangas (2015). The prediction models for parameters $b_{0}$ and $b_{1}$ were fitted as linear mixed effects model in $R$ using the Ime function.

Table 1. Height models predicted from assortments volume. The commercial volume (Vcom) is the sum of the saw $\log (L o g)$ and pulpwood (Pulp) volume. DDY is the long-time average degree days using a $5{ }^{\circ} \mathrm{C}$ threshold temperature. The random components $s\left(b_{0_{i}}\right)$ and $s\left(b_{1 i}\right)$ are the stand-specific (i) constant and coefficient, respectively. The term $\mathrm{s}\left(\mathrm{e}_{\mathrm{ij}}\right)$ is a scale parameter for the variance function, and the final standard deviation can be calculated as $\mathrm{s}_{\mathrm{yi}}=\mathrm{s}\left(\mathrm{e}_{\mathrm{ij}}\right)(1000 / D D Y)^{p}$. For pine, this number is $0.257(1000 / D D Y)^{0.914}$.

| Parameter | Pine |  | Spruce |  | Birch |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $b_{0}$ | Estim. | Std. | Estim. | Std. | Estim. | Std. |
